

Vanna x AI Agents: Practical Product Ideas for Delphi

Why This Matters

Vanna is not just a trading UI. It is a composable credit infrastructure layer for DeFi: users deposit collateral once, borrow undercollateralized capital, and deploy that capital across spot, perps, yield, prediction markets, and future venues through unified smart margin accounts.

The strongest AI opportunity for Vanna is not generic portfolio advice. It is making Vanna the credit, risk, and execution layer that AI agents can safely use. Delphi's current AI x crypto thesis points toward trust infrastructure, agentic finance, real revenue, and durable data moats. Vanna maps well to that because it already has the hard primitive most agent systems do not have: credit.

The market is also moving in this direction. Coinbase x402 has made paid API access machine-readable for agents. Stellar now supports x402-style agentic payments with Soroban authorization. Base MCP has shown that users increasingly want AI clients like ChatGPT, Claude, Cursor, and Codex to interact directly with wallets and DeFi protocols. Vanna should not compete as another chatbot. Vanna should become the agent-native credit and risk layer.

Shortlisted Practical Ideas

1. Agent-Native Margin Copilot

A chat-to-trade agent for Vanna users. The user expresses intent in plain language, such as "open a conservative 3x long XLM position and avoid liquidation," and the agent handles the full workflow: collateral selection, borrowing amount, venue routing, execution, position monitoring, and risk controls.

This is the most user-facing AI product because it turns Vanna's complex margin flow into a single intent-based experience. It also makes the protocol easier for non-professional traders while still preserving guardrails such as max leverage, minimum health factor, max loss, allowed assets, and user approval thresholds.

Why it matters: Vanna can own the trader relationship at the UX layer while increasing borrow demand and trading volume.

2. Vanna MCP + CLI Credit Rails

A developer and trader interface that exposes Vanna through MCP, CLI, and SDK tools. Traders using Claude Code, Cursor, custom bots, or institutional agent frameworks can query Vanna risk state, open and close positions, borrow, repay, rebalance, and route trades without using the frontend.

This should be built as an agent-access layer rather than only as developer documentation. The MCP server should expose typed tools such as `get_account_state`, `estimate_borrow_capacity`, `simulate_position`, `open_position`, `repay_debt`, `rebalance_collateral`, and `protect_position`.

Why it matters: This makes Vanna available inside the tools where agent builders already work. It is the fastest path to making Vanna programmable by external agents.

3. Agent Credit Layer

Vanna becomes the credit primitive for capital-constrained AI agents. Most agent payment and wallet systems assume the agent already has capital. Vanna can solve the missing layer: if an agent has a strong behavioral record, it can access undercollateralized credit through Vanna and deploy it into approved strategies.

The credit decision can start simple: health factor discipline, repayment behavior, liquidation history, position duration, collateral diversity, and realized PnL discipline. Over time, this becomes a deeper underwriting system for agents and automated strategies.

Why it matters: This is a platform-level idea, not a feature. If agents become economic actors, they will need credit. Vanna can be the agent credit layer.

4. Portable Agent Identity + Credit Score

A queryable Vanna Agent Score that follows an agent across protocols. The score is based on repayment history, liquidation avoidance, leverage discipline, account longevity, drawdown control, and historical behavior inside Vanna smart margin accounts.

Other protocols could query this score before allowing an agent to borrow, route large trades, access premium data, or participate in strategy markets. The score can initially be off-chain and later become verifiable through signed attestations or on-chain proofs.

Why it matters: Smart contracts can be forked, but high-quality credit history cannot be forked. This is one of Vanna's strongest possible data moats.

5. Vanna x402 Financial Data API

A paid, per-request API layer for agent-readable financial data. Agents can pay via x402-style flows to access Vanna data endpoints such as credit scores, liquidation risk, borrow rates, yield opportunities, position state, available credit, and risk simulations.

Possible endpoints:

- /account-state/{address} - current collateral, debt, health factor, available credit, and positions.
- /simulate-position - expected health factor, liquidation price, borrow cost, and slippage before execution.
- /agent-score/{address} - Vanna Agent Score and key risk factors.
- /yield-rates - available yield opportunities across supported venues.
- /risk-alerts/{address} - liquidation and deleverage risk signals.

Why it matters: This creates real revenue from Vanna's data layer. It also turns Vanna into infrastructure that other agents and protocols can pay to use.

6. Liquidation Protection + Risk Guardian Agent

A practical near-term agent that protects traders from liquidation. The agent monitors health factor and executes defensive actions within user-set policies: alert the user, add collateral, repay debt, reduce leverage, hedge exposure, or close a portion of the position.

The first version should be policy-based, not fully autonomous black-box trading. Users define rules such as minimum health factor, max daily deleverage, allowed protective actions, and whether human approval is required above certain thresholds.

Why it matters: Liquidation fear is one of the biggest blockers for leveraged DeFi usage. A risk guardian directly improves user confidence, retention, and borrow demand.

7. Intent-Based Prime Brokerage

A future-facing product where agents submit financial goals and Vanna resolves them using credit, collateral, risk controls, and execution routing. Example: "Get \$500K ETH exposure, keep health factor above 1.4, use the cheapest borrow route, and park idle collateral in yield."

This moves Vanna from a margin protocol into an onchain prime brokerage layer. The agent or user provides the financial intent; Vanna supplies credit, risk simulation, venue routing, and post-trade monitoring.

Why it matters: Intent systems route capital. Vanna can create and manage capital through undercollateralized credit. That is the deeper primitive.

8. DePIN / GPU Financing Credit Agent

A longer-term credit product for AI infrastructure operators. Vanna could finance GPU operators or DePIN compute providers using agent-assisted underwriting: hardware value, uptime, revenue history, compute market rates, repayment behavior, and collateral quality. This should not be pitched as a near-term build unless Vanna has a clear oracle and legal/collateral path. But strategically, it aligns tightly with Delphi's interest in AI infrastructure financing and crypto-native yield.

Why it matters: It extends Vanna's credit rails beyond trading and into AI infrastructure debt, which can become a differentiated source of yield.

Recommended Priority

Near term:

- Agent-Native Margin Copilot.
- Vanna MCP + CLI Credit Rails.
- Liquidation Protection + Risk Guardian Agent.
- Vanna x402 Financial Data API.

Mid term:

- Agent Credit Layer.
- Portable Agent Identity + Credit Score.

Long term:

- Intent-Based Prime Brokerage.
- DePIN / GPU Financing Credit Agent.

What To Tell Delphi

The strongest framing is: Vanna is building the credit and risk layer for agentic finance. Most agent infrastructure today focuses on wallets, payments, prompts, and execution. Those are important, but they assume the agent already has capital and already knows how to manage risk. Vanna fills the missing layer: undercollateralized credit, unified risk, liquidation protection, and eventually portable credit history for agents.

A simple pitch:

"AI agents can already pay for APIs, control wallets, and call DeFi tools. What they cannot do yet is access disciplined credit and manage margin safely. Vanna is building that layer. Our near-term products are an agent-native margin copilot, MCP/CLI credit rails, and a liquidation protection agent. The long-term moat is behavioral credit data: every agent and trader using Vanna builds a credit history that cannot be forked."
